CERTIFIED BY

ASSOCIATE PROFESSOR DR. JASON TEO TZE WI
SUPERVISOR

ACKNOWLEDGMENT

First and foremost, I would like to thank my supervisor, Associate Professor Dr. Jason Teo Tze Wi for his patience, constructive guidance and motivation that lead to the completion of this thesis. Not forgetting, to my examiner and panel, Dr. Lau Hui Keng and Dr. Norazlina Khamis for their critical views and ideas about my project.

Additionally, I would like to thank my family and friends for their unconditional support, help and insights.

Last but not least, an utmost thanks and gratitude to God for His grace.

ABSTRACT

Dynamic optimization problems have become increasingly popular to solve in computational science. As real world problems are becoming more complex day by day, dynamic optimization problems have become an alternative platform for the application of heuristics methods. A higher class of heuristics, called metaheuristics has been a popular choice in solving optimization problems because of their ability to adapt to uncertainties and is not biased to any specific problem. One of the well-known classes of metaheuristics is swarm intelligence, inspired by the behavior of animal swarm in the nature. Ant Colony System and Particle Swarm Optimization are two instances of swarm intelligence. Bat algorithm on the other hand is one of the latest swarm intelligence proposed. It has been applied to many continuous and discrete problem domains. In this research, we will attempt to apply hybrid bat algorithm with local search to solve a well-established dynamic combinatorial problem, which is the dynamic traveling salesman problem (DTSP). The experiments included in this thesis are the parameter tuning of the bat algorithm parameters and then using those parameters to determine the optimal settings. The settings are then used in the bat algorithm framework to compare with other metaheuristics such as ACO and ACO with local search. As we have proposed two variants of the bat algorithm, we found that from the experiments, the second proposed variant which is the bat algorithm with natural frequency performs better compared to the bat algorithm with the original proposed frequency across all benchmarks and dynamic test cases. However, the proposed algorithms were still unable to outperform the conventional ACO and hybridized ACO algorithms. Nevertheless, their performances are enhanced by the hybridization of the 2-Opt local search.

ABSTRAK

Masalah pengoptimuman dinamik merupakan masalah yang semakin popular untuk diselesaikan di dalam bidang pengkomputeran sains. Masalah dunia sebenar yang semakin kompleks telah menjadikan masalah pengkomputeran sebagai platform alternatif untuk pengaplikasian kaedah heuristik. Kaedah heuristik yang lebih sofistikated, juga dikenali sebagai metaheuristik merupakan pilihan yang popular untuk menyelesaikan masalah pengoptimuman dinamik disebabkan kemampuan mereka untuk mengadaptasi kepada ketidakpastian dan tidak menyebelahi mana-mana masalah yang spesifik. Salah satu kelas metaheuristik yang terkenal adalah kecerdasan kawanan, yang diinspirasikan daripada perlakuan kawanan haiwan semula jadi. Antara kecerdasan kawanan yang telah dicadangkan adalah sistem koloni semut dan pengoptimuman kawanan partikel. Algoritma kelawar pula merupakan salah satu kecerdasan kawanan yang telah dicadangkan baru-baru ini. Ia telah diaplikasikan di dalam pelbagai masalah domain diskret dan lanjutan. Di dalam kajian ini, kami akan cuba untuk mengaplikasi algoritma kelawar dengan strategi carian tempatan untuk menyelesaikan masalah kombinatorik dinamik iaitu masalah perjalanan jurujual dinamik. Eksperimen yang telah dijalankan termasuklah pengoptimuman parameter algoritma kelawar dan perbandingan antara nilai optima yang diperolehi dari algoritma kelawar yang dicadangkan, sistem koloni semut dan sistem koloni semut yang telah dihibridasikan dengan strategi carian tempatan. Kita telah mencadangkan dua jenis algoritma kelawar dan hasil daripada eksperimen eksperimen yang dilakukan, kita mendapati bahawa algoritma jenis kedua mempunyai nilai optima yang lebih baik untuk setiap kes perjalanan. Walaupun begitu, prestasi algoritma yang dicadangkan kurang memberangsangkan kerana nilai optima yang diperolehi kurang jika dibandingkan dengan algoritma semut and versi semut yang dihibridasikan dengan carian tempatan. Namun, ini membuktikan bahawa sesuatu algoritma itu dapat dipertingkatkan dari segi efisien melalui penambahan strategi carian tempatan.

GLOSSARY OF RESEARCH KEY TERMS AND PHRASES

Benchmark problem	A standardized and specific problem for assessing the performance of algorithms
Combinatorial	Related to finite discrete domain variables
Continuous	Related to varying continuously real-valued variables
Domain	Defines the scope where the problem occurs
Dynamic	A consistent change in state over a period of time
Evolutionary Computation	Subfield of artificial intelligence that involves combinatorial and continuous optimization problems
Non-polynomial	Is the set of decision problems where the “yes” instances can be accepted in polynomial time by a deterministic Turing machine
Optimization problem	Problem of finding best solution from all feasible solutions
Problem instances	A set of computational problems that usually falls under the same category
Static	A fixed and unchanged state over a period of time

LIST OF ABBREVIATIONS

ABC - Artificial Bee Colony

ACO - Ant Colony Optimization

ACS - Ant Colony System

AES - Agent-based Evolutionary Search

ALS - Annealing with Learning Scheme

APF - Annealed Particle Filter

ASTP-GA - Asymmetric Traveling Salesman Genetic Algorithm

BA - Bat Algorithm

BAM - Bat Algorithm with Mutation

BAST - Bat Algorithm based on Scheduling Tool

BBA - Binary Bat Algorithm

BBO - Biogeograph-based Optimization

CBA - Chaotic Bat Algorithm

CS - Cuckoo Search

CS-GRASP - Cuckoo Search with Greedy Randomized Adaptive Search Procedure

CVRP - Capacitated Vehicle Routing Problem

CWS - Clark and Wright Savings

DABA - Directed Artificial Bat Algorithm

DBA - Discrete Bat Algorithm

DBG - Dynamic Benchmark Generator

DCOP - Dynamic Combinatorial Optimization Problem

DE - Differential Evolution

DIOEA - Dynamic Inver-over Evolutionary Algorithm

DOP - Dynamic Optimization Problem

DPSO - Dynamic Particle Swarm Optimization

DTSP - Dynamic Traveling Salesman Problem

EC - Evolutionary Computing

FA - Firefly Algorithm

FLBA - Fuzzy Logic Bat Algorithm

GA - Genetic Algorithm

GRASP - Greedy Randomized Adaptive Search Procedure

GSA - Gravitational Search Algorithm

HBA - Hybrid Bat Algorithm

HBA-PR - Hybridized Bat Algorithm with Path Relinking

HS - Harmony Search

IBA - Improved Bat Algorithm

IEEE - Institute of Electrical and Electronics Engineers

ILS - Iterated Local Search

MMRE - Mean Magnitude of Relative Error

MOBA - Multi-Objective Bat Algorithm

NP - Non-deterministic Polynomial time

PBIL - Population-based Incremental Learning

PF - Particle Filter

PGA - Parallel Genetic Algorithm

PSO - Particle Swarm Optimization

RFD - River Formation Dynamic

SA - Simulated Annealing

SD - Standard Deviation

SGA - Simple Genetic Algorithm

SOP - Static Optimization Problem

SSPF - Scatter Search Particle Filter

SR-GCWS - Simulation via Routing in the Generalized Clark and Wright Savings

STSP-GA - Symmetric Traveling Salesman Problem Genetic Algorithm

TLBO - Teaching and Learning Based Optimization

TS - Tabu Search

TSP - Traveling Salesman Problem

TSPLIB - Library of sample instances for TSP (and related) instances

XOR - Exclusive OR

LIST OF MATHEMATICAL SYMBOLS

Σ - Sum of

\neq - Not equal to

$=$ - Equal to

$>$ - Greater than

$<$ - Less than

\leq - Less greater than or equal to

\in - Belong to

O - Big O notation

\approx - Rounded to

$\%$ - Percentage of

CHAPTER 1

INTRODUCTION

1.1 Overview

This chapter will examine the research topic which is hybridizing bat algorithm with discrete local search for solving dynamic traveling salesman problem (DTSP) from different aspects. The aspects include introduction to the problem background, problem statement, hypothesis, objectives and scope of research. In problem background, we will briefly explain the Traveling Salesman Problem (TSP), DTSP and why they remain difficult to solve till these days. TSP and DTSP will also be defined in this section. In problem statement section, we will briefly justify the use of metaheuristics method especially the bat algorithm in solving DTSP. For hypothesis, we will state the expected outcome for implementing bat algorithm with local discrete search in DTSP. We will further state the objectives and the scope for the research before settling on the organization of this report.

1.2 Problem Background

There are many core open problems still exist in the computational complexity theory that remain challengingly unsolved. One of the problems is non-polynomial (NP) hard problems where no efficient algorithm is known as they cannot be solved in polynomial time. In this context, Traveling Salesman Problem (TSP) would be the most famous case of NP hard problem. Till these days, TSP remains the most intensively studied problem in computational mathematics. The main objective for TSP can be described as simple as finding the shortest possible route while traveling exactly once across a set of cities that consists of certain distances and eventually returning to the starting city with minimal total distance. The solution

space for TSP problem can be extremely large depending on the number of cities. In other words, it increases exponentially with the number of cities. Variants of TSP have also existed which the most crucial being the Dynamic Traveling Salesman Problem (DTSP). DTSP is basically the generalization of classic TSP where changes can be introduced by adding or deleting cities, swapping location of cities or changing the value of pairwise distances. After changes are introduced, the salesman needs to re-plan his route. Many real world optimization problems are dynamic optimization problems (DOPs) where changes may occur over time regarding the objective function, decision variable, constraints and others. Therefore, DTSP is one of the useful benchmark problems that can be used to emulate the real dynamic traffic scenario. For example, exchangeable cities and traffic factors where the global optimum value is unknown during the environment.

1.2.1 Definition of Traveling Salesman Problem (TSP)

In order to create an algorithm framework for DTSP, we have to define TSP first. It can be described as follows: Given a collection of cities and pairwise distances of the cities, we need to find the shortest path that starts from one city and visits each of the other cities once and only once before returning to the starting city. The main objective is to minimize the sum of distances used to visit the entire tour. Usually the problem is represented by a fully connected weighted graph $G = (N, A)$, where $N = \{0, \dots, n\}$ is a set of nodes and $A = \{(i, j) : i \neq j\}$ is a set of arcs. The collection of cities is represented by the set N and the connections between them by the set A . Each connection (i, j) is associated with a non-negative value d_{ij} which represents the distance between cities i and j . TSP can be formally described as follows:

$$f(x) = \min \sum_{i=0}^n \sum_{j=0}^n d_{ij} \psi_{ij}$$

Subject to:

$$\psi_{ij} = \begin{cases} 1, & \text{if } (i, j) \text{ is used in the tour} \\ 0, & \text{otherwise} \end{cases}$$

Where $\psi_{ij} \in \{0, 1\}$, n is the number of the cities and d_{ij} is the distance between city i and j . Each city $i \in N$ has a location defined by (x, y) and each connection $(i, j) \in A$ is associated with a non-negative distance d_{ij} .

1.2.2 Definition of DTSP

In this paper, the DTSP functions as the platform to change any static instances for conventional TSP into a dynamic environment where the fitness landscape remains unchanged but the algorithm will be inclined to be shifted to search for different parts of fitness landscape between time intervals. Since the encoding of the problems changes, the DTSP can be defined as:

$$D(t) = \{d_{ij}(t)\}_{n(t) \times n(t)}$$

Where $d_{ij}(t)$ is the cost from city i and j , t is the real world time. The number of cities $n(t)$ and the cost matrix are time dependent.

1.3 Problem Statement

Traditional method such as brute force search is infeasible to be applied to solve TSP. Therefore, the use of heuristics and exact methods are widely accepted instead to solve TSP. A more versatile heuristics, which is the metaheuristics has gained popularity in recent years due to its flexibility which can be used as the black-box approach. Nevertheless, applying metaheuristics method can solve TSP or DTSP more efficiently in terms of the quality of the optimal solutions. Through this research, we will implement a relatively new metaheuristics, bat

algorithm with local search to solve DTSP, considering its potential in various fields of optimization problems.

1.4 Hypothesis

Hybridization of bat algorithm with local search strategy will improve the chances of finding a good quality of optimal solution. The quality of the optimal solution in this context shall be based on comparison of optimal solutions obtained in the hybridized bat algorithms and other metaheuristics methods.

1.5 Objectives of Research

- a. To design and implement proposed an improved metaheuristic algorithm which is the hybridized bat algorithm with local discrete search to solve DTSP.
- b. To deploy and test hybridized bat algorithm with local discrete search to solve DTSP.
- c. To verify the performance of hybridized bat algorithm with local discrete search by direct comparison with other heuristics and metaheuristics for solving DTSP.

1.6 Scope of Research

Our research will focus on the application of recently developed nature inspired algorithm which is bat algorithm, which will be hybridized with local discrete search in solving traveling salesman problem with a dynamic environment (as the benchmark problem) only and not solving other optimization problems. In order to demonstrate the effectiveness of the algorithm, several well known problem instances have been selected from the IEEE competition website in regard of the benchmark problem (Mavrovouniotis, Li, Yang and Yao, 2013). The problem instances consist of seven cities, namely eil51, kroA100, kroA150, kroA200, lin318, and pr439. In between testing and performing the algorithm to solve DTSP, some research might
