

Observation of the Bile Canaliculi of *Puntius javanicus* Liver affected by Copper

Abstract

Investigation on in vivo effects of copper (Cu) on the ultrastructure of *P. javanicus* liver was carried out using transmission electron microscopy (TEM). The addition of sublethal concentration of 5 mg/L of Cu caused abnormalities on the bile canaliculi (BC) including dilation and elongation compared to control and at lower concentrations of copper with a normal round shape form. Findings from this study support an alternative histological assessment of the effects of Cu concentration on *P. javanicus* liver.
