

Adinandra longipedicellata

ABSTRACT

Adinandra longipedicellata is known only from Telupid and Beluran areas, Sabah. It is locally common in forest near river with ultramafic geology in Sabah. The estimated area of occupancy (AOO) and extent of occupancy (EOO) are 28 km² and 497 km² respectively. Although the AOO is calculated from known existing records, it is considered that the actual AOO may be considerably larger than this due to under sampling. The localities are within protected areas and there is no continuing decline. There are no major threat for this species. Therefore, it is assessed as Least Concern. *Adinandra longipedicellata* is endemic to Borneo, and confined to Sabah, Malaysia.
