ACKNOWLEDGEMENT

First and foremost, I would like to thank God, for the opportunity given to me and the strength upon the completion of this study. Through His greatest power and love, He had shown me a glimpse of understanding of just a fraction of His vast creation for the benefit of science. I personally would like to express my deepest gratitude to the people who have been helping me and contributing to my research. It is a great honor to know and to meet these people that has helped me making this research and thesis into a successful completion.

I would like to express my deep and sincere appreciation to my supervisor, Prof. Dr. Chye Fook Yee for his valuable advices, patient guidance and encouragement throughout this master study. His patience in sharing his knowledge kindly and experience by giving advices as well as encouragement and motivation lead me in order to completion of this thesis.

I would like to be grateful to my course mate in giving me helpful opinions and suggestion throughout the entire research study. Besides that, I would like to show appreciation to Faculty of Food Science and Nutrition (FSMP) laboratory technicians, assistants and seniors for their willingness to help and cooperation on the instrument operations and reagent as well as apparatus requirement during my laboratory work. Most of all, I dedicate my deepest love to my parents and family members for their endless physically and spiritually support and encouragement throughout my research project.

ABSTRACT

Probiotic has been previously used for the treatment and prevention of intestinal disorders caused by enteropathogens. However, the antagonistic effect of probiotic on these pathogens in the gastrointestinal tract is not fully understood. The study aims to investigate the antagonistic ability of a probiotic strain, *Lactobacillus plantarum* 0612 against the adhesion of selected foodborne enteropathogens (*Escherichia coli* ATCC 11775, *Salmonella* Enteritidis ATCC 13076, *Listeria monocytogenes* ATCC 13932 and *Vibrio parahaemolyticus* ATCC 17802) to the colon epithelial Caco-2 cells by exclusion, competition and displacement conditions. *L. plantarum* 0612 has been subjected to the gastrointestinal transits simulation (GITS) sequentially prior to assess its competitive inhibition on selected human pathogenic strains using intestinal epithelial cells with different colonic pH conditions. The surface layer proteins that are involved in adhesion inhibition were separated using SDS-PAGE and further identified by MALDI-TOF/MS. Results showed that the adhesion of *E. coli* and *L. monocytogenes* on to Caco-2 cells was significantly inhibited by *L. plantarum* 0612 with a reduction of 4.35 log CFU/ml and 4.14 log CFU/ml, respectively in exclusion mechanism. However, *L. plantarum* 0612 exhibited a significantly stronger ($p < 0.05$) competition activity against *V. parahaemolyticus* as compared to its exclusion and displacement activity. The exclusion and competition mechanisms seemed to be more effective against the colonization of *E. coli* in the presence of *L. plantarum* 0612. The GITS exposed *L. plantarum* 0612 showed significantly higher ($p < 0.05$) efficacy of competitive inhibition against the selected foodborne enteropathogens in all colonic conditions as compared to the unexposed strain. The highest antagonistic activity was observed against the adhesion of *E. coli* and *V. parahaemolyticus* on the Caco-2 cells, with a log reduction of 5.10 log CFU/ml and 4.53 log CFU/ml respectively, in the colonic pH 5.0 after 8 hours of exposure. However, the GITS exposed *L. plantarum* 0612 significantly reduced ($p < 0.05$) the adhesion of *L. monocytogenes* (4.20 log reduction) and *S. Enteritidis* (4.12 log reduction) respectively in the same colonic condition. It seems the colonic pH of the intestines could influence the antagonism of *L. plantarum* 0612 with the highest anti-adhesion against the bacterial pathogens was shown at pH 5.0 and 6.0, signifying the protective role of probiotic in the human proximal colon. Six cell surface-associated proteins (30s ribosomal protein, ATP synthase subunit beta, enolase, phosphoglycerate kinase, lactate dehydrogenase, and glyceraldehyde-3-phosphate dehydrogenase) and 6 adhesive moonlighting proteins, (elongation-factor Tu, 60 kDa chaperonin GroEL, pyruvate kinase, triosephosphate isomerase, and 2, 3 bisphosphoglycerate-dependant phosphoglycerate mutase fructose-bisphosphate aldolase) have been identified using MALDI-TOF/TOF mass spectrometry. The expression of these adhesive surface proteins seemed to be influenced by the colonic pH conditions. Therefore, the existing of surface adhesive proteins in *L. plantarum* 0612 is expected to be responsible for its adhesion and antagonistic effects against the foodborne enteropathogens in human colonic epithelial cells. The excellent adherence and the antagonistic properties of *L. plantarum* 0612 against the enteropathogens are promising for the prevention and management of foodborne infections/diseases.

ABSTRAK

AKTIVITI ANTAGONISTIK *Lactobacillus plantarum* 0612 TERHADAP ENTEROPATHOGEN BAWAAN MAKANAN TERPILIH

Probiotik telah digunakan selama ini untuk tujuan rawatan dan pencegahan masalah gangguan usus yang disebabkan oleh enteropatogen. Namun, kesan antagonis probiotik terhadap patogen dalam saluran gastrousus masih belum difahami secara mendalam. Kajian ini bertujuan untuk mengetengahkan keupayaan dan kesan antagonistik melalui penyingkiran, persaingan dan penyesaran strain probiotik *Lactobacillus plantarum* 0612 terhadap pelekatan empat jenis enteropatogen bawaan makanan (*Escherichia coli* ATCC 11775, *Salmonella enteritidis* ATCC 13076, *Listeria monocytogenes* ATCC 13932 dan *Vibrio parahaemolyticus* ATCC 17802) di permukaan sel usus Caco-2. Inokulasi *L. plantarum* 0612 ke dalam simulasi transit gastrousus (GITS) berurutan dinilai dari segi perencatan persaingannya ke atas strain patogen bawaan makanan terpilih dengan menggunakan sel epitelium usus dalam keadaan pH kolon yang berbeza. Protein dari lapisan permukaan dinding sel yang terlibat dalam perencatan lekatan telah dianalisis dan dikenalpasti menggunakan SDS-PAGE dan MALDI-TOF/MS. Hasil kajian menunjukkan bahawa kesan rencatan melalui mekanisma penyingkiran *E. coli* dan *L. monocytogenes* pada permukaan sel Caco-2 oleh *L. plantarum* 0612 adalah sangat ketara dengan penurunan masing-masing sebanyak 4.35 log CFU/ml dan 4.14 log CFU/ml. Namun, toleransi GITS *L. plantarum* 0612 ($p < 0.05$) terhadap aktiviti persaingan adalah jauh lebih kuat terhadap *V. parahaemolyticus* berbanding dengan aktiviti pengecualian dan penyesaran. Mekanisma pengecualian dan persaingan seolah-olahnya lebih berkesan terhadap perencatan *E. coli* dengan kehadiran *L. plantarum* 0612. *L. plantarum* 0612 terdedah GITS menunjukkan keberkesanannya yang ketara ($p < 0.05$) terhadap perencatan kompetitif enteropathogens bawaan makanan yang dipilih dalam semua keadaan kolon berbanding dengan strain yang tidak terdedah. Aktiviti antagonistik tertinggi *L. plantarum* 0612 ditunjukkan terhadap pelekatan *E. coli* dan *V. parahaemolyticus* pada sel Caco-2, dengan pengurangan masing-masing sebanyak 5.10 log CFU / ml dan 4.53 log CFU / ml selepas pendedahan 8 jam kepada kolon pH 5.0. Walau bagaimanapun, *L. plantarum* 0612 terdedah GITS berkurangan ($p < 0.05$) terhadap *L. monocytogenes* (pengurangan log 4.20) dan *S. Enteritidis* (pengurangan log 4.12) dalam keadaan kolon yang sama. Ini menunjukkan yang pH kolon usus boleh mempengaruhi kesan antagonistik *L. plantarum* 0612 dengan nilai anti-lekatan yang paling tinggi terhadap patogen bakteria telah ditunjukkan pada pH 5.0 dan 6.0. sekaligus menyokong keberkesanan perlindungan probiotik dalam usus proksimal manusia. Enam protein dari lapisan permukaan dinding sel yang berkaitan (30s protein ribosom, ATP synthase subunit beta, enolase, phosphoglycerate kinase, dehidrogenase laktat, dan glycealdehyde-3-fosfat dehidrogenase) dan 6 pelekat "moonlighting protein", (pemanjangan faktor-Tu, 60 kDa chaperonin GroEL, pyruvate kinase, isomerase triosephosphate, dan 2, 3 bisphosphoglycerate phosphoglycerate mutase) telah dikenal pasti menggunakan spektrometri jisim MALDI-TOF/TOF. Ekspresi protein pelekat dari permukaan dinding sel seolah-olah dipengaruhi oleh keadaan pH kolon. Oleh itu, protein pelekat yang sedia ada di permukaan dinding sel *L. plantarum* 0612 dijangka bertanggungjawab untuk memberi kesan lekat dan kesan antagonistik terhadap enteropathogen bawaan makanan pada sel-sel epitelium kolon manusia.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Foodborne disease becomes an accumulative public health problem that is responsible for an extensive morbidity and mortality globally. Various pathogens (bacteria, viruses, and parasites) are known to cause more than 250 foodborne diseases of which the majority of deaths are caused by diarrheal diseases (Fleury *et al.*, 2008; Linscott, 2011). Food safety has emerged as a key global issue with international trade and public health implications. Among the bacterial pathogens, *Escherichia coli*, *Salmonella spp.*, *Listeria monocytogenes*, *Vibrio spp.*, *Campylobacter jejuni*, *Yersinia enterocolitica* and *Staphylococcus aureus* are the most important foodborne pathogens and represent a major public health problem worldwide. In general, all of the foodborne pathogens must compete with gut microflora to colonize in the human gastrointestinal (GI) tract specifically in the large intestine, where huge amounts of resident microbiota are colonized (Lawley and Walker, 2013). Some of these bacterial pathogens evolved the abilities to resist non-specific host defences, such as stomach acidity, peristalsis, mucosal cell exfoliation, intestinal mucins, and bacteriocins (dos Reis and Horn, 2010), adhere to intestinal epithelial and eventually colonize the epithelia, cause infection/illnesses to the host. Foodborne pathogens such as *Escherichia coli*, *Salmonella*, and *Listeria monocytogenes* caused numerous gastrointestinal illnesses and death (CDC, 2013). The ability of acid- and/or bile- resistant enteric bacteria through the gastric transit increases their possibility of colonization on the intestinal lining and caused infection/illnesses (Thomas, Ockhuizen, and Suzuki, 2014).

In human gastrointestinal tract (GIT), it is crucial to maintain the intestinal microflora density as it increases from 10^1 – 10^4 microbial cells in the stomach and duodenum, 10^4 – 10^8 cells in the jejunum and ileum, 10^{10} – 10^{12} cells in the colon and faeces (Booijink *et al.*, 2007; Dethlefsen *et al.*, 2006). The transit time in the large

intestine is highly variable, with range of 6-32 hours typically reported (Cook *et al.*, 2012). The pH values of the large intestine have been reported to lie within 5.26-6.72 (ascending colon) and 5.20-7.02 (descending colon). The reduction in the normal microflora has adverse effects on human well-being and can be frequently associated with greater host susceptibility to enteric pathogenic infection. Thus, administration of probiotics has been recognized to overcome problems associated with microflora imbalance, improving both gastrointestinal and general health.

Probiotics are "live microorganisms that when administered in adequate amounts confer a beneficial health effect on the host" (Boué *et al.*, 2016). The emergence of concept "probiotics" had created niche development in the food industry. Most probiotic strains used in the food industry belong to the lactic acid bacteria (LAB), especially from *Lactobacillus* and *Bifidobacterium* genus. LAB are the focus of probiotic research internationally and their health benefits include prevention of diarrhea (Wanke and Szajewska, 2014), reduction of cholesterol level (Jones *et al.*, 2012), pediatric atopic dermatitis prevention (Panduru *et al.*, 2015), relief of irritable bowel syndrome (Yoon *et al.*, 2014) and efficacy in management of lactose intolerance (Almeida *et al.*, 2012). Besides, the competitive exclusion properties of probiotics as well as their ability to displace and inhibit pathogens are most important for therapeutic manipulation of the enteric microbiota (Molinaro *et al.*, 2012; Ortiz *et al.*, 2014). Therefore, application of such approaches can contribute to expand the beneficial properties of the selected probiotics on human health against pathogen infection. However, the beneficial effects of the probiotics are known to be genus, species and strain specific against selected enteric pathogens (Shi *et al.*, 2016). Therefore, it is crucial to consider a particular probiotic strain for its effective and potential therapeutic use.

Despite of all the benefits discussed upon ingestion of LAB, it is suggested that the microorganisms must be capable to survive through gastrointestinal tract with low pH environment and destructive bile salt (Vandenplas *et al.*, 2015). Besides, the potential probiotic must be able to adhere and colonize the intestinal cell wall, which is necessary to trigger any direct interactions between probiotic and host cells leading to the competitive exclusion of pathogens and modulation of host

cell responses (Van Baarlen *et al.*, 2013). Moreover, it must exhibit significant antimicrobial activity against pathogenic bacteria while remain safe for human consumption (Bull *et al.*, 2013). In addition, the probiotic selected must be able to survive and retain their functionality upon passing through the harsh industrial processing operations so that the dose supplemented is sufficient to proliferate in the gut, thus provide the beneficial properties to the host (Sánchez *et al.*, 2012). Some studies demonstrated the ability of probiotic bacteria to inhibit the colonization of *Escherichia coli* and *Clostridium difficile* from human intestinal epithelial cells (Tejero-Sarinena *et al.*, 2012; Schoster *et al.*, 2013). In fact, both *L. crispatus* (Chen *et al.*, 2007) and *L. helveticus* (Johnson-Henry *et al.*, 2009; Wine *et al.*, 2009) have been shown to competitively exclude enteropathogenic bacteria from Caco-2 epithelial cells. *L. paracasei* subsp. *paracasei* M5-L, *L. rhamnosus* J10-L and *L. casei* Q8-L were effective in inhibiting adhesion of *S. sonnei* to HT-29 cells (Zhang *et al.*, 2010). The competitive exclusion by probiotic is based on a bacteria-to-bacteria interaction mediated by the competition for the available nutrients and adhesion sites (Bermudez-Brito *et al.*, 2012). Nevertheless, the degree of competition is strain dependent (Johnson *et al.*, 2016).

The knowledge related to probiotic tremendously arisen in recent years, yet the underlying functional mechanisms of probiotic are still not fully understood. It is widely accepted that adhesion and colonization of probiotics to the intestinal mucosa is considered as one of the most important selection criterion for persistent beneficial effects of probiotics (García-Cayuela *et al.*, 2014; Verdenell *et al.*, 2014). The initial adhesion stage of the probiotic bacteria to intestinal cell wall involves complex physiochemical interactions including hydrophobicity and charges (Ramos *et al.*, 2013; Yadav *et al.*, 2015). The surface proteins are expected to give appreciable effects on the properties of the cell wall of many *Lactobacillus* strains. Indigenous lactobacilli often showed the presence of specific, highly basic, hydrophobic cell surface proteins (Wasko *et al.*, 2014). Surface molecules are likely to play an important role in establishment of colonization and may be involved in the exclusion of intestinal pathogens (Antikainen *et al.*, 2007). Certain probiotics are found to utilize proteinaceous components, such as surface layer proteins (SLPs) to adhere on the intestinal cells (Meng *et al.*, 2014). The SLPs are two-dimensional,

highly porous crystalline arrays of subunits that presents the outermost structure of cell envelope in bacteria composed of glycoproteins or proteins, which represents up to 15% total protein of the bacterial cell (de sa Peixoto *et al.*, 2015). SLPs mediating bacterial adhesion to intestinal mucosa and epithelial cells have been demonstrated for many *Lactobacillus* species (Roselli *et al.*, 2016). Besides acting as cell adhesion mediators, SLPs are also believed to be capable of maintaining the cellular shape as well as playing an important role as immune modulators (Hynönen and Palva, 2013).

Recently, microbiologists have been exploring proteomics as a tool in research on adaptation of microorganisms to their environment. Several multifunctional proteins have been identified as associated with the cell surface and/or in the extracellular space. *L. plantarum* was found in many habitats and is a naturally occurring species in the gastro-intestinal tract of humans and animals. Cell surface glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as well as elongation factor Tu (EF-Tu), triosephosphate isomerase, and enolase were identified on the surface of *Lactobacillus plantarum* as molecules mediating adhesion to intestinal epithelial cells (Dhanani and Bagchi, 2013; Jensen *et al.*, 2014; Zhang *et al.*, 2015). Interestingly, surface proteins of lactobacillus are revealed to play an important role in inhibiting pathogens. Given that surface layer protein forms the outermost layer of gram-positive bacteria, this protein may potentially play a role in competitive exclusion of pathogens (Johnson-Henry *et al.*, 2007; Chen *et al.*, 2007). Surface layer protein was identified on the outer surface of *L. plantarum* 423, where it is supposed to play a role in adhesion to Caco-2 cells, as well as in the competitive exclusion of *Clostridium sporogenes* and *Enterococcus faecalis* (Ramiah *et al.*, 2008). After removal or disruption of the surface proteins from *Lactobacillus* species, the ability of adhesion and inhibition against pathogens decreased (do Carmo *et al.*, 2016; Bouchard *et al.*, 2013). Nevertheless, the use of new molecular omics-based technologies is tremendously increasing and it will apparently replace traditional screening methods. Omics technologies may also turn out to be very effective in the follow-up analysis of probiotic candidate strains resulting from *in vitro* and/or *in vivo* screening with current methodologies. Therefore, we hypothesize that GIT exposed *L. plantarum* 0612 could antagonize against the adhesion of selected
